Space Resources Roundtable –SRR IX

October 26, 2007

Golden, Colorado

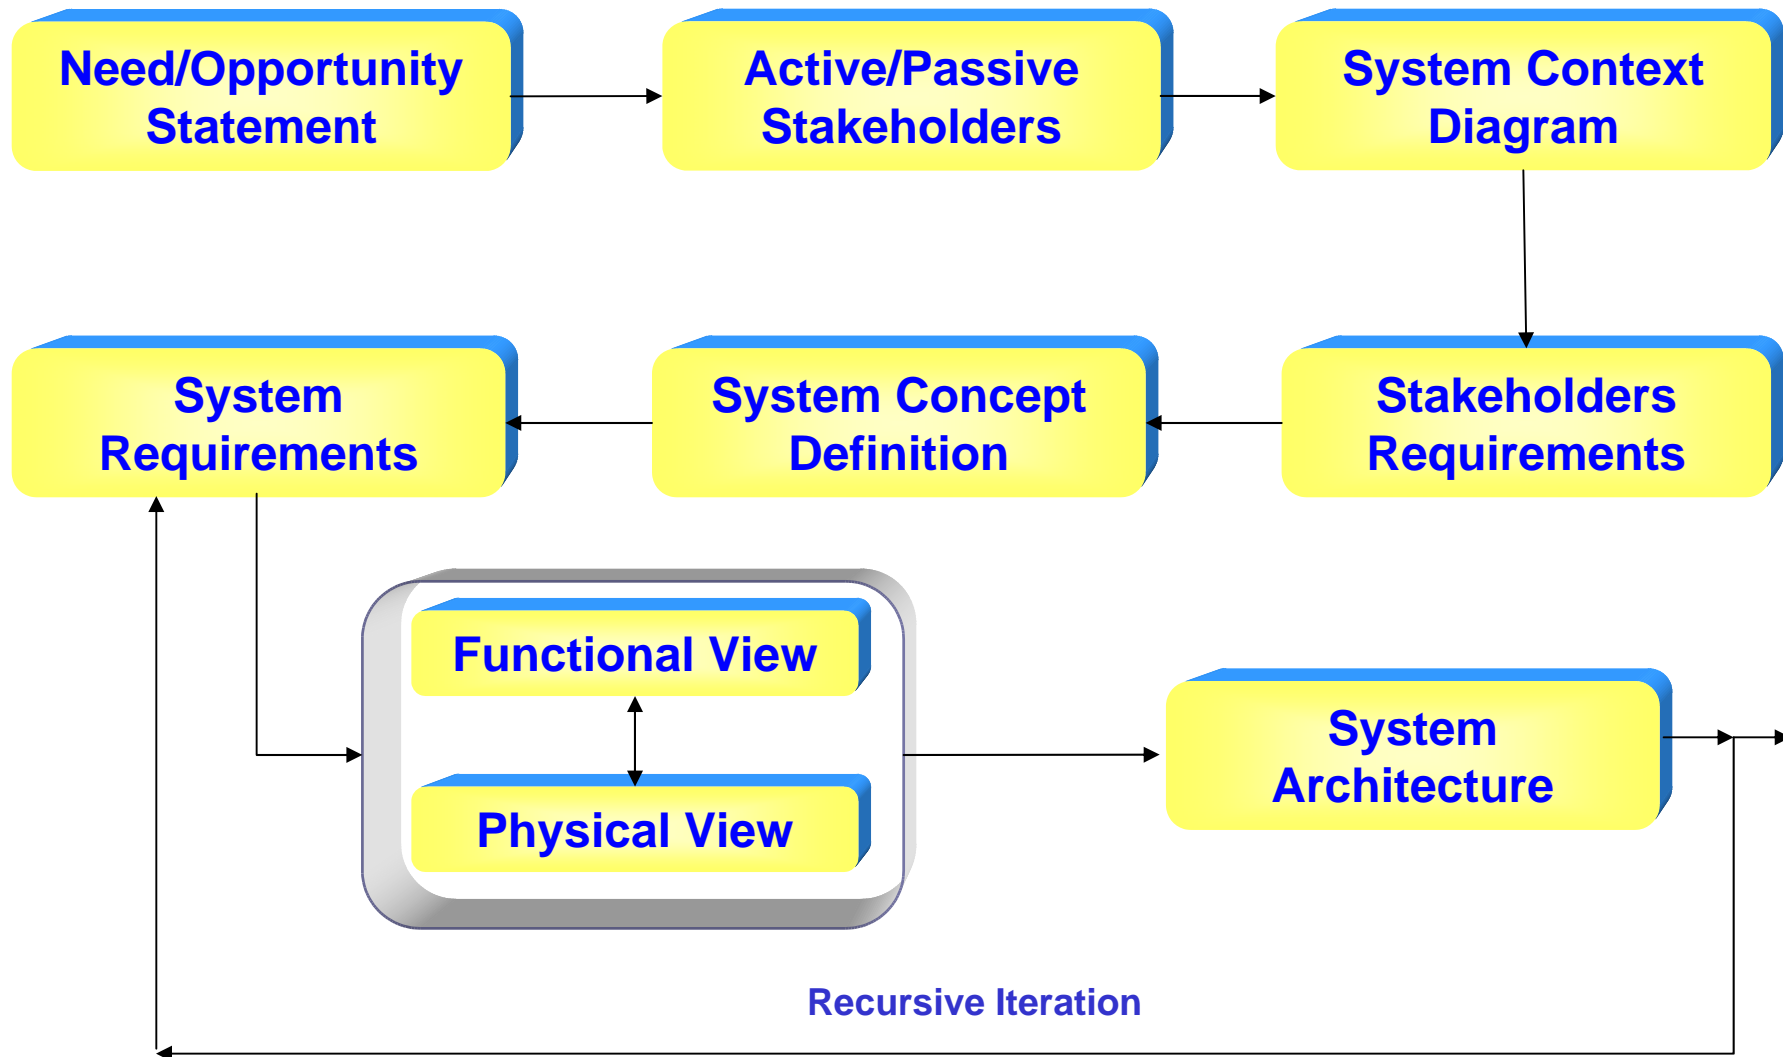

# Agenda

- Systems Engineering Approach to Lunar Outpost Excavation
- Exploration Architecture & Constellation Program Requirements
- Lunar Outpost Architectures: LAT I and LAT II
- Types of Lunar Excavation
- Excavation Tasks for a NASA Lunar Outpost
- Manifest / Concept of Operations
- Excavation Requirements – Option 1
- Excavation Requirements – Option 2
- Key Performance Parameters
- Regolith Properties
- Excavation Concept Evaluation Criteria
- Conclusion

# Typical Systems Engineering Process

# Space Opportunities

- John F. Kennedy, 1962

**"I believe that this nation should commit itself to achieving the goal, before this decade is out, of landing a man on the moon and returning him safely to the earth.**

- George W. Bush, 2004

**"...return to the moon by 2020, as the launching point for missions beyond, with the goal of living and working there for increasingly extended periods of time."**

## Vision for Space Exploration Requirements (Strategic)

Based on results from the Vision for Space Exploration (VSE), 5 of the top 40 requirements for returning to the Moon are directly related to ISRU.

- Develop and validate tools, technologies and systems to extract and process resources on the Moon, with extension to other exploration destinations.
- Produce propellants, life support and other consumables from lunar resources
- Characterize and quantify the resource potential of the Moon.
- Demonstrate ISRU technologies and systems to reduce risk for mission integration and commercial development.
- Investigate and develop technologies and systems that effectively utilize lunar resources and products.

# Objectives for Lunar Exploration & Beyond

- [EARD-Ex-0004] The Exploration Architecture shall demonstrate resource extraction from in-situ materials during lunar missions. [CA0006-HQ]
- *Rationale:* Establishes the priority of extraction and use of resources from the lunar environment. Extraction and utilization demonstrations can serve as a first step in utilizing lunar resources (if desirable), or in demonstrating a capability that may be further exploited during human missions to Mars.
- [CA0006-HQ] The Constellation Architecture **shall provide the capability to demonstrate resource extraction and utilization from in situ materials** during lunar missions.
- *Rationale:* Establishes the priority of extraction and use of resources from the lunar environment. Extraction and utilization demonstrations can serve as a first step in utilizing lunar resources (if desirable), or in demonstrating a capability that may be further exploited during human missions to Mars

# Supportability & ISRU Consumable Production

- [EARD 3.2.7.6 Supportability] “... **Using in-situ surface resources to produce propellants, breathing gases, and possibly consumable water could significantly reduce the mass that must be delivered to planetary surfaces.**
- [CARD 3.1.3.6.7 Supportability]: The logistics footprint required to support exploration missions must be minimized... **Utilization of in-situ surface resources for production of propellants, breathing gases, and possibly consumable water could significantly reduce the mass that must be delivered to planetary surfaces...**
- [EARD 4.1.1.1.3 Stockpiling and Outpost Completion]: “... ISRU will begin to come online near the end of this phase, reducing the reliance on consumables from Earth.
- [CA0353-PO] **Draft** The Constellation Architecture shall be capable of utilizing predeployed surface infrastructure.
  - *Rationale:* The Constellation Architecture **elements will be able to utilize functionality contained within pre-deployed infrastructure** to meet outpost mission requirements. Pre-deployed mission assets could include surface infrastructure such as habitats, power systems, **in-situ resource utilization equipment**, exploration elements, and landing navigation beacons.
- [EARD 4.1.2.1.4.1 In-Situ Resource Utilization]: The outpost will **operate ISRU elements to allow for extraction of water and oxygen from the lunar surface.** Production units, transportation capability, and storage facilities are all necessary for the extraction of consumables from the surface. The lunar outpost will leverage the extracted resources to supplement its water and oxygen requirements. NASA may identify other uses for lunar resources as well.
- [EARD-Cx-0008] **By 2023, the Constellation Architecture should provide from lunar in-situ resources, no less than 1 metric ton of oxygen per year.**
- [EARD-Cx-0011] **By 2027, the Constellation Architecture should produce no less than 10 metric tons of oxygen per year using lunar in-situ resources.**

# LAT I Architecture – December 2006

- Human lunar missions will be used to build an outpost at a polar site
- The ability to fly human sorties and cargo missions with the human lander will be preserved
- Initial power architecture will be solar with the potential augmentation of nuclear power at a later time

## *Architectural Options Under Evaluation*

**Option 1: All elements delivered with crewed flights (LAT 1)**

**Option 2: Derivative of LAT 1 except uncrewed lander can deliver hardware to surface provided all elements must be sized to fit on a crewed lander.**

**Option 3: A single large, fully outfitted and pre-integrated Habitation launched and landed on a single uncrewed mission**

**Option 4: The lander has integrated surface mobility (mobile lander)**

~~**Option 5: Long range, pressurized rover delivered as early in the sequence as possible**~~ (Captured in each)

**Option 6: Nuclear power used for the surface power in lieu of solar**

## *Hybrid Approach to Options*

**A flexible architecture incorporating best features and lessons learned from all the Lunar Architecture Team options**

**Surface Architecture - Discrete elements sized smaller than the monolithic unit, but larger than the mini-hab concept**

- **Cargo lander needed for robustness**
- **Outpost built up from only 2 or 3 of these elements**
- **Assembly facilitated from separate surface mobility system**
- **Make maximum use of delivered hardware to minimize the bone yard**

## *Hybrid Approach to Options (cont.)*

Capability for global access and extended range surface exploration is essential

- **Surface Mobility**
  - Early delivery of small, agile pressurized rover that carries SPE protection, suit lock (not like Apollo)
  - Utilize common elements from surface carrier where possible (e.g. wheel/motor units)

# Lunar Outpost Excavation Study

- Examined LAT I Architecture
- Examined LAT II Architecture
- Study is based on LAT II, Option 1 & Option 2 only
- Too many options to examine them all
- Functional Decomposition by Mission Manifest (Reference EARD Rev G 122106)
- Identified Lunar Outpost Elements
- Developed an associated notional Concept of Operations (ConOps)
- Identified discrete Excavation tasks in the ConOps
- Examined the total excavation needs by task
- Proceeded with a chronological identification of excavation needs
- Delivered results to ISRU Systems Modeling team for systems level analysis
- Determined Mars Forward Links

# LAT II Architecture – September 2007

Option 1 – Mini-habitat elements with Crew Lander (LAT-1)   
Option 2 – Mini-habitat elements with Crew/Cargo Lander

*Friendly to Commercial, IP roles  
Flexible to redirection  
Tolerant to loss of element*

*Assembly and maintenance intensive  
Extensive unloading, transportation,  
emplacement and integration*

# Regolith Excavation & Material Handling Overview

## Develop Capabilities for Lunar Regolith Excavation and Material Handling, Sized for Efficient Lunar Outpost Operations

- Excavate, collect and deliver unconsolidated surface regolith for use as feedstock in *oxygen production* and *solar-wind volatile* extraction.
- Excavate, collect and deliver consolidated subsurface regolith for *polar-volatile extraction* in permanently shadowed polar craters.
- Excavate, collect, contour and stabilize surface and subsurface regolith for *lunar site preparation* including burying habitat and reactor modules, construction of berms, launch/landing surfaces, roads, etc.
- Remove processed regolith from oxygen or volatile extraction plants.

Excavation for O<sub>2</sub> Production

Excavation for Volatiles

Mining Polar Water

Excavation for Site Prep

**This study addresses Excavation for O<sub>2</sub> Production, Polar H<sub>2</sub>O & Site Preparation Only**

# Regolith Excavation Study

---

- Excavation Criteria are determined by:
  - Lunar Outpost Configuration, ConOps and Associated Elements
  - Excavation Tasks and Outpost Needs
  - Lunar Environment
  - Space Transportation Architecture and Capability
  - Supportability and Life Cycle Requirements

The steps followed in this study to evaluate the specific criteria were:

- Specify the excavation tasks by careful study of the lunar outpost development plans.
- Determine the functional requirements for excavation.
- Develop a list of criteria for ranking alternative excavation concepts.
- Organize the criteria with a hierarchy.

# Excavation Tasks

- Regolith Mining for O<sub>2</sub> Production
- H<sub>2</sub>O Ice/Regolith Mining from Shadowed Craters
- Landing / Launch Pads
- Blast Protection Berms
- Electrical Cable Trenches
- Utility Roads / Clearing Obstacles
- Foundations / Leveling
- Trenches for Habitat & Element Burial
- Regolith Shielding on Roof over Element Trenches

# Artist's Landing Pad Concept

# Aerial Views of Landing Pad

Landing Pad = 50 m Diameter

Margin of Error for Landing = 2 Vehicle Diameters each side (20 m)

# Landing Pad Concept

Based on current analysis from Plume Ejecta Team

- Landing pad and berms is largest outpost emplacement excavation requirement
  - 871 MT of regolith moved for every pad/berm prepared
- If landers are not moved, a new pad needs to be prepared *every 6 months*
  - Single pad can potentially be used for Option 4 - mobile landers

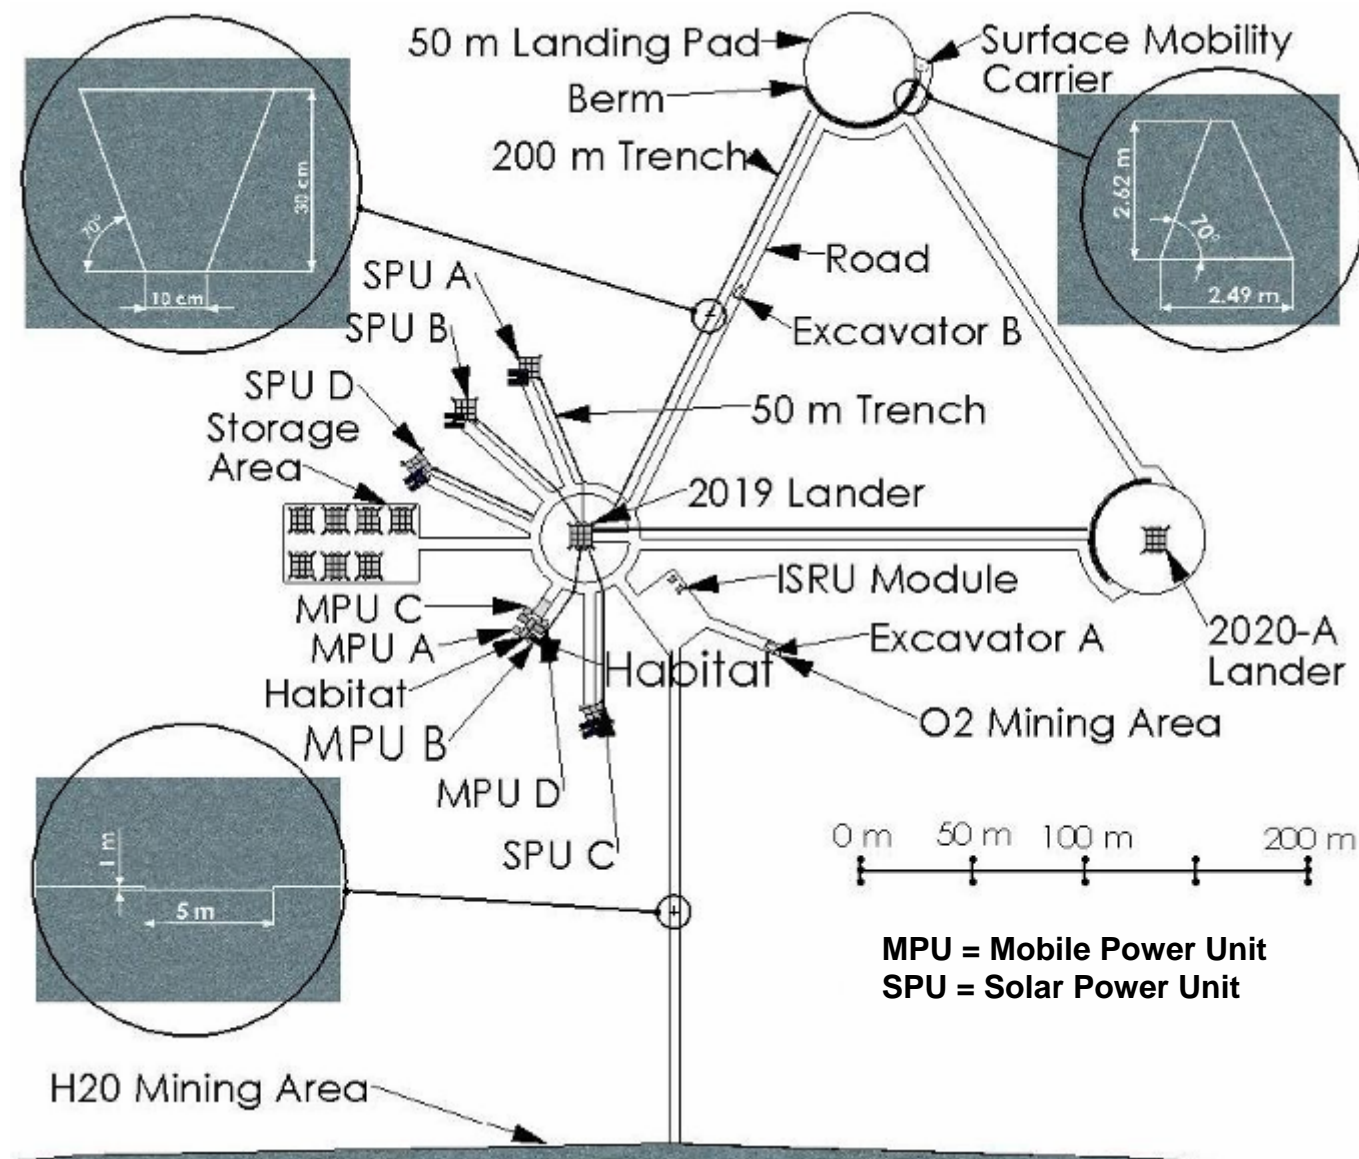

| <b>Landing Pad</b>  | <b>Min.</b> | <b>Max.</b> |
|---------------------|-------------|-------------|
| •Pad Diameter:      | 50 m        | 100 m       |
| •Depth of scraping: | 0.2 m       | 0.2 m       |

| <b><u>Berms</u></b>    | <b><u>Min.</u></b> | <b><u>Max.</u></b> |
|------------------------|--------------------|--------------------|
| •Pad Diameter:         | 50 m               | 100 m              |
| •Plume ejecta ang:     | 3°                 | 3°                 |
| •Berm Height:          | 1.31 m             | 2.62 m             |
| •Berm Height w/margin: | 1.5 m              | 3 m                |
| •Top Width             | 0.3 m              | 0.3 m              |
| •Bottom Width:         | 1.39 m             | 2.49 m             |

degrees

## Habitat Regolith Shielding - Requirements

- Requires 323 MT excavation of compacted regolith and 100 MT of backfill/covering per 6 months for 4 missions
- ~30% of total outpost emplacement requirements
  - Second highest requirement after landing pads

| q <sub>all</sub> | kPa               | 2         |                                     |            | 3       |

**Z = depth in cm**

**D50 = Particle size where 50% passes this sieve opening size**

**D95 = Particle size where 95% passes this sieve opening size**

**G = Specific Gravity**

**ρ = bulk density**

**D<sub>R</sub> = Relative density**

**T = soil temperature**

**Slope Angle, β<sub>E</sub> = Excavated Slope Angle (F.S. = 1.5),**

**β<sub>C</sub> = Compacted Pile Slope Angle**

**β<sub>D</sub> = Dumped Pile Slope Angle (Angle of Repose)**

**q<sub>ult</sub> = Ultimate Static Bearing Capacity,**

**q<sub>all</sub> = Allowable Static Bearing Capacity (at 1 cm allowable settlement)**

**Shear strength is defined by Mohr's equation:**

$$\tau = \sigma \tan \phi + c$$

**Where τ = shear strength,**

**φ = internal friction angle,**

**σ = normal stress, and c = cohesion**

**The equation that defines sliding stress is:**

$$S = \sigma \tan \delta + C_a$$

**Where S = sliding stress, δ = the angle of sliding friction,**

**σ = normal stress, and C<sub>a</sub> = adhesion**

# Conclusion: Excavation Concepts Evaluation

The Excavation Concept Requirements, KPP's & Evaluation Criteria, in conjunction with regolith properties, analysis and Lunar Environment considerations provide a method for evaluation of various alternative excavation system concepts for a Lunar Outpost
